Figure S1

Supplemental Figure 1. Pattern of IOP history in glaucoma model eyes over the five week period following episcleral vein injections. IOP measurements were made three times per week, so daily data points charted reflect a subset of glaucoma model eyes. Each point on the chart represents mean IOP± SEM for at least five experimental eyes. Overall, for both treatment groups, there is a linear increase in IOP with time, but within experimental groups considerable IOP variation exists both between eyes and between days. Linear regression of daily tonolab reading means to days post- injection are indicated by lines for each treatment. The differences between these lines are not significant.
