Supplementary Figure S2

Supplementary FIGURE S2: Fibronectin and vimentin whole mount staining was not useful to distinguish between CECs and circulating fibrocytes / dendritic derivatives in FECD. FECD whole mounts showed diffuse expression of fibronectin (n = 1) and vimentin (n = 1) proteins, making it impossible to discern, count and localize cells with different morphologies. Whereas for collagen I (n = 4), immunoreactivity was only present in the central zone of the CE layer, and individual cells expressing collagen I could be discerned.
